1. Abstract

In this paper we propose and study a technique to impose structural constraints on the output of a neural network, which can reduce amount of computation and number of parameters besides improving prediction accuracy when the output is known to approximately conform to the low-rankness prior. The technique proceeds by replacing the output layer of neural network with the so-called MLM layers, which forces the output to be the result of some Multilinear Map, like a hybrid-Kronecker-dot product or Kronecker Tensor Product. In particular, given an “autoencoder” model trained on SVHN dataset, we can construct a new model with MLM layer achieving 62% reduction in total number of parameters and reduction of ℓ_2 reconstruction error from 0.088 to 0.004. Further experiments on other autoencoder model variants trained on SVHN datasets also demonstrate the efficacy of MLM layers.

2. Introduction

To the human eyes, images made up of random values are typically easily distinguishable from those images of real world. In terms of Bayesian statistics, a prior distribution can be constructed to describe the likelihood of an image being a natural image. An early example of such “image prior” is related to the frequency spectrum of an image, which assumes that lower-frequency components are generally more important than high-frequency components, to the extent that one can discard some high-frequency components when reducing the storage size of an image, like in JPEG standard of lossy compression of images (Wallace, 1991).

Another family of image prior is related to the so called sparsity pattern (Candes et al., 2006, Candès et al., 2006, Candes et al., 2008), which refers to the phenomena that real world data can often be constructed from a handful of exemplars modulo some negligible noise. In particular, for data represented as vector $\mathbf{d} \in \mathbb{F}^m$ that exhibits sparsity, we can construct the following

approximation:

$$\mathbf{d} \approx \mathbf{D}\mathbf{x}, \quad (1)$$

where $\mathbf{D} \in \mathbb{F}^{m \times n}$ is referred to as dictionary for $\mathbf{d}$ and $\mathbf{x}$ is the weight vector combining rows of the dictionary to reconstruct $\mathbf{d}$. In this formulation, sparsity is reflected by the phenomena that number of non-zeros in $\mathbf{x}$ is often much less than its dimension, namely:

$$\|\mathbf{x}\|_0 \ll m. \quad (2)$$

The sparse representation $\mathbf{x}$ may be derived in the framework of dictionary learning (Olshausen and Field, 1997, Mairal et al., 2009) by the following optimization:

$$\min_{\mathbf{x}} \|\mathbf{M} - \sum_i x_i \mathbf{D}_i\|_F + \lambda f(\mathbf{x}), \quad (3)$$

where $\mathbf{D}_i$ is a component in dictionary, f is used to induce sparsity in $\mathbf{x}$, with ℓ_1 being a possible choice.

2.1 Low-Rankness as Sparse Structure in Matrices

When data is represented as a matrix $\mathbf{M}$, the formulation of 3 is related to the rank of $\mathbf{M}$ by Theorem ?? in the following sense:

$$\text{rank}(\mathbf{M}) = \min_{\mathbf{x}} \|\mathbf{x}\|_0 \quad (4)$$

$$\text{s.t. } \mathbf{M} = \sum_i x_i \mathbf{D}_i, \quad (5)$$

$$\mathbf{D}_i = \mathbf{u}_i \mathbf{v}_i^\top, \mathbf{u}_i^\top \mathbf{u}_i = \mathbf{1}, \mathbf{v}_i^\top \mathbf{v}_i = \mathbf{1}. \quad (6)$$

Hence a low rank matrix $\mathbf{M}$ always has a sparse representation w.r.t. some rank-1 orthogonal bases. This unified view allows us to generalize the sparsity pattern to images by requiring the underlying matrix to be low-rank.

When an image has multiple channels, it may be represented as a tensor $\mathcal{T} \in \mathbb{F}^{C \times H \times W}$ of order 3. Nevertheless, the matrix structure can still be recovered by unfolding the tensor along some dimension.

In Figure 1, it is shown that the unfolding of the RGB image tensor along the width dimension can be well approximated by a low-rank matrix as energy is concentrated in the first few components.

In particular, given Singular Value Decomposition of a matrix $\mathbf{M} = \mathbf{U}\mathbf{D}\mathbf{V}^*$, where $\mathbf{U}, \mathbf{V}$ are unitary matrices and $\mathbf{D}$ is a diagonal matrix with the diagonal made up of singular values of $\mathbf{M}$, a rank- k approximation of $\mathbf{M} \in \mathbb{F}^{m \times n}$ is:

$$\mathbf{M} \approx \mathbf{M}_k = \tilde{\mathbf{U}} \tilde{\mathbf{D}} \tilde{\mathbf{V}}^*, \tilde{\mathbf{U}} \in \mathbb{F}^{m \times k}, \tilde{\mathbf{D}} \in \mathbb{F}^{k \times k}, \tilde{\mathbf{V}} \in \mathbb{F}^{n \times k}, \quad (7)$$

where $\tilde{\mathbf{U}}$ and $\tilde{\mathbf{V}}$ are the first k -columns of the $\mathbf{U}$ and $\mathbf{V}$ respectively, and $\tilde{\mathbf{D}}$ is a diagonal matrix made up of the largest k entries of $\mathbf{D}$.

In this case approximation by SVD is optimal in the sense that the following holds (Horn and Johnson, 1991):

$$\mathbf{M}_r = \inf_{\mathbf{X}} \|\mathbf{X} - \mathbf{M}\|_F \text{ s.t. } \text{rank}(\mathbf{X}) \leq r, \quad (8)$$

Figure 1: An illustration of the singular values of the unfolding of an RGB sample image.

and

$$\mathbf{M}_r = \inf_{\mathbf{X}} \|\mathbf{X} - \mathbf{M}\|_2 \text{ s.t. } \text{rank}(\mathbf{X}) \leq r. \quad (9)$$

An important variation of the SVD-based low rank approximation is to also model the ℓ_1 noise in the data:

$$\|\mathbf{M}\|_{RPCA} = \inf_{\mathbf{S}} \|\mathbf{M} - \mathbf{S}\|_* + \lambda \|\mathbf{S}\|_1. \quad (10)$$

This norm which we tentatively call “RPCA-norm” (Candès et al., 2011), is well-defined as it is infimal convolution (Rockafellar, 2015) of two norms.

2.2 Low Rank Structure for Tensor

Above, we have used the low-rank structure of the unfolded matrix of a rank-3 tensor corresponding to RGB values of an image to reflect the low rank structure of the tensor. However, there are multiple ways to construct matrix $\mathbf{D} \in \mathbb{R}^{m \times 3n}$, e.g., by stacking $\mathbf{R}$, $\mathbf{G}$ and $\mathbf{B}$ together horizontally. An emergent question is if we construct a matrix $\mathbf{D}' \in \mathbb{R}^{3m \times n}$ by stacking $\mathbf{R}$, $\mathbf{G}$ and $\mathbf{B}$ together vertically. Moreover, it would be interesting to know if there is a method that can exploit both forms of constructions. It turns out that we can deal with the above variation by enumerating all possible unfoldings. For example, the nuclear norm of a tensor may be defined as:

Definition 1 Given a tensor $\mathcal{E}$, let $\mathbf{E}_{(i)} = \text{fold}_i^{-1}(\mathcal{E})$ be unfolding of $\mathcal{E}$ to matrices. The nuclear norm of $\mathcal{E}$ is defined w.r.t. some weights β_i (satisfying $\beta_i \geq 0$) as a weighted sum of the matrix nuclear norms of unfolded matrices $\mathbf{E}_{(i)}$ as:

$$\|\mathcal{E}\|_* = \sum_i \beta_i \|\mathbf{E}_{(i)}\|_*. \quad (11)$$

Consequently, minimizing the tensor nuclear norm will minimize the matrix nuclear norm of all unfoldings of tensor. Further, by adjusting the weights used in the definition of the tensor nuclear norm, we may selectively minimize the nuclear norm of some unfoldings of the tensor.

2.3 Stronger Sparsity for Tensor by Kronecker Product Low Rank

When an image is taken as matrix, the basis for low rank factorizations are outer products of row and column vectors. However, if data exhibits Principle of Locality, then only adjacent rows and columns can be meaningfully related, meaning the rank in this decomposition will not be too low. In contrast, local patches may be used as basis for low rank structure (Elad and Aharon, 2006, Yang et al., 2008, Schaeffer and Osher, 2013, Dong et al., 2014b, Yoon et al., 2014). Further, patches may be grouped before assumed to be of low-rank (Buades et al., 2005, Hu et al., 2015, Kwok, 2015).

A simple method to exploit the low-rank structure of the image patches is based on Kronecker Product SVD of matrix $\mathbf{M} \in \mathbb{F}^{m \times n}$:

$$\mathbf{M} = \sum_{i=1}^{\text{rank}(\mathcal{R}(\mathbf{M}))} \sigma_i \mathbf{U}_i \otimes \mathbf{V}_i, \quad (12)$$

where $\mathcal{R}(\mathbf{A})$ is the operator defined in (Van Loan, 2000, Van Loan et al., 1993) which shuffles indices.

$$\mathcal{R}(\mathbf{A} \otimes \mathbf{B}) = \text{vec } \mathbf{A} (\text{vec } \mathbf{B})^\top. \quad (13)$$

Note that outer product is a special case of Kronecker product when $\mathbf{A} \in \mathbb{F}^{m \times 1}$ and $\mathbf{B} \in \mathbb{F}^{1 \times n}$, hence we have SVD as a special case of KPSVD. The choice of shapes of $\mathbf{A}$ and $\mathbf{B}$, however, affects the extent to which the underlying sparsity assumption is valid. Below we give an empirical comparison of a KPSVD with SVD. The image is of width 480 and height 320, and we approximate the image with KPSVD and SVD respectively for different ranks. To make the results comparable, we let $\mathbf{B} \in \mathbb{F}^{16 \times 20}$ to make the number of parameters in two approach equal.

We may extend Kronecker product to tensors as Kronecker Tensor Product as:

Definition 2 *Kronecker tensor product (Phan et al., 2013, 2012) is defined for two tensors of the same order k . I.e., for two tensors:*

$$\mathcal{A} \in \mathbb{F}^{m_1 \times m_2, \dots, \times m_k}, \quad (14)$$

and

$$\mathcal{B} \in \mathbb{F}^{n_1 \times n_2, \dots, \times n_k}, \quad (15)$$

we define Kronecker product of tensor as

$$(\mathcal{A} \otimes \mathcal{B})_{i_1, i_2, \dots, i_k} := A_{\lfloor i_1/m_1 \rfloor, \lfloor i_2/m_2 \rfloor, \dots, \lfloor i_k/m_k \rfloor} B_{i_1 \bmod m_1, i_2 \bmod m_2, \dots, i_k \bmod m_k} \quad (16)$$

where

$$\mathcal{A} \otimes \mathcal{B} \in \mathbb{F}^{m_1 n_1 \times m_2 n_2, \dots, \times m_k n_k}. \quad (17)$$

With the help of Kronecker Tensor Product, (Phan et al., 2013, 2012) is able to extend KPSVD to tensors as:

$$\mathcal{T} = \sum_{i=1}^{\text{rank}(\mathcal{R}(\mathcal{T}))} \sigma_i \mathcal{U}_i \otimes \mathcal{V}_i, \quad (18)$$

where $\mathcal{R}(\mathcal{T})$ is a matrix.

(a) Original image selected from BSD500 dataset (Arbelaez et al., 2011)

(b) SVD approximations with rank 1, 2, 5, 10, 20 respectively from left to right

(c) KPSVD approximations with right matrix having shape 16x20 and with rank 1, 2, 5, 10, 20 respectively from left to right

Figure 2: This figures visually compares the results of KPSVD and SVD approximation given the same number of parameters. For this example, it can be seen that KPSVD with right matrix shape 16x20 is considerably better than SVD in approximation.

3. Prediction Regularization by Structural Constraint

In a neural network like

$$\inf_{\theta} d(\mathbf{Y}, f(\mathbf{X}; \theta)), \quad (19)$$

If $f(\mathbf{X}; \theta)$, the prediction of the network, is known to be like an image, it is desirable to use the image priors to help improve the prediction quality. An example of such a neural network is the so-called ‘‘Autoencoder’’ (Vincent et al., 2008, Deng et al., 2010, Vincent et al., 2010, Ng, 2011), which when presented with a possibly corrupted image, will output a reconstructed image that possibly have the noise suppressed.

One method to exploit the prior information is to introduce an extra cost term to regularize the output as

$$\inf_{\theta} d(\mathbf{Y}, \mathbf{Z}) + \lambda r(\mathbf{Z}) \text{ s.t. } \mathbf{Z} = f(\mathbf{X}; \theta), \quad (20)$$

The regularization technique is well studied in the matrix and tensor completion literature (Liu et al., 2013, Tomioka et al., 2010, Gandy et al., 2011, Signoretto et al., 2011, Kressner et al., 2013, Bach et al., 2012). For example, nuclear norm $\|\mathbf{Z}\|_*$, which is sum of singular values, or logarithm of determinant $\log(\det(\epsilon\mathbf{I} + \mathbf{Z}\mathbf{Z}^\top))$ (Fazel et al., 2003), may be used to induce low-rank structure if $\mathbf{Z}$ is a matrix. It is even possible to use RPCA-norm to better handle the possible sparse non-low-rank components in $\mathbf{Z}$ by letting $r(\mathbf{Z}) = \|\mathbf{Z}\|_{RPCA}$.

However, using extra regularization terms also involve a few subtleties:

1. The training of neural network incurs extra cost of computing the regularizer terms, which slows down training. This impact is exacerbated if the regularization terms cannot be efficiently computed in batch, like when using the nuclear norm or RPCA-norm regularizers together with the popular mini-batch based Stochastic Gradient Descent training algorithm (Bottou, 2010).
2. The value of λ is application-specific and may only be found through grid search on validation set. For example, when r reflects low-rankness of the prediction, larger value of λ may induce result of lower-rank, but may cause degradation of the reconstruction quality.

We take an alternative method by directly restricting the parameter space of the output. Assume in the original neural network, the output is given by a Fully-Connected (FC) layer as:

$$\mathbf{L}_a = h(\mathbf{L}_{a-1}\mathbf{M}_a + \mathbf{b}_a). \quad (21)$$

It can be seen that the output $\mathbf{L}_a \in \mathbb{F}^{m \times n}$ has mn number of free parameters. However, noting that the product of two matrices $\mathbf{A} \in \mathbb{F}^{m \times r}$ and $\mathbf{B} \in \mathbb{F}^{r \times n}$ will have the property

$$\text{rank}(\mathbf{AB}) \leq r, \quad (22)$$

when $m \geq r$ and $n \geq r$.

Hence we may enforce that $\text{rank}(\mathbf{L}_a) \leq r$ by the following construct for example:

$$\mathbf{L}_a = h(\mathbf{L}_{a-1}\mathbf{M}_a + \mathbf{b}_a)h(\mathbf{L}_{a-1}\mathbf{N}_a + \mathbf{c}_a), \quad (23)$$

when we have:

$$\mathbf{L}_{a-1}\mathbf{M}_a + \mathbf{b}_a \in \mathbb{F}^{m \times r} \quad (24)$$

$$\mathbf{L}_{a-1}\mathbf{N}_a + \mathbf{c}_a \in \mathbb{F}^{r \times n}. \quad (25)$$

In a Convolutional Neural Network where intermediate data are represented as tensors, we may enforce the low-rank image prior similarly. In fact, by proposing a new kind of output layer to explicitly encode the low-rankness of the output based on some kinds of Multilinear Map, like a hybrid of Kronecker and dot product, or Kronecker tensor product, we are able to increase the quality of denoising and reduce amount of computation at the same time. We outline the two formulations below.

Assume each output instance of a neural network is an image represented by a tensor of order 3:

$$\mathcal{T} \in \mathbb{F}^{C \times H \times W}, \quad (26)$$

where C , H and W are number of channels, height and width of the image respectively.

3.1 KTP layer

In KTP layers, we approximate $\mathcal{T}$ by Kronecker Tensor Product of two tensors.

$$\mathcal{T} \approx \mathcal{A} \otimes \mathcal{B}. \quad (27)$$

As by applying the shuffle operator defined in (Van Loan, 2000, Van Loan et al., 1993), 28 is equivalent to:

$$\mathcal{R}(\mathcal{T}) \approx \text{vec } \mathcal{A} \text{vec } \mathcal{B}^\top, \quad (28)$$

hence we are effectively doing rank-1 approximation of the matrix $\mathcal{R}(\mathcal{T})$. A natural extension would then be to increase the number of components in approximation as:

$$\mathcal{T} \approx \sum_{i=1}^K \mathcal{A}_i \otimes \mathcal{B}_i. \quad (29)$$

We may further combine the multiple shape formulation of 29 to get the general form of KTP layer:

$$\mathcal{T} \approx \sum_{j=1}^J \sum_{i=1}^K \mathcal{A}_{ij} \otimes \mathcal{B}_{ij}. \quad (30)$$

where $\{\mathcal{A}_{ij}\}_{i=1}^K$ and $\{\mathcal{B}_{i,j}\}_{i=1}^K$ are of the same shape respectively.

3.2 HKD layer

In HKD layers, we approximate $\mathcal{T}$ by the following multilinear map between $\mathcal{A} \in \mathbb{F}^{C_1 \times H_1 \times W_1}$ and $\mathcal{B} \in \mathbb{F}^{C_1 \times C_2 \times H_2 \times W_2}$, which is a hybrid of Kronecker product and dot product:

$$T_{c,h,w} \approx \tilde{T}_{c,h,w} = \tilde{T}_{c,h_1+H_1*h_2,w_1+W_1*w_2} = \sum_{c_1} A_{c_1,h_2,w_2} B_{c,c_1,h_1,w_1}, \quad (31)$$

where $h = h_1 h_2$, $w = w_1 w_2$.

The rationale behind this construction is that the Kronecker product along the spatial dimension of H and W may capture the spatial regularity of the output, which enforces low-rankness; while the dot product along C would allow combination of information from multiple channels of $\mathcal{A}$ and $\mathcal{B}$.

In the framework of low-rank approximation, the formulation 31 is by no means unique. One could for example improve the precision of approximation by introducing multiple components as:

$$T_{c,h,w} = T_{c,h_1+H_1*h_2,w_1+W_1*w_2} \approx \sum_k \sum_{c_1} A_{k,c_1,h_2,w_2} B_{k,c,c_1,h_1,w_1}. \quad (32)$$

Hereafter we would refer to layers constructed following 31 as HKD layers. The general name of MLM layers will refer to all possible kinds of layers that can be constructed from other kinds of multilinear map.

3.3 General MLM layer

A Multilinear map is a function of several variables that is linear separately in each variable as:

$$f: V_1 \times \cdots \times V_n \rightarrow W, \quad (33)$$

where $V_1, \dots, V_n$ and W are vector spaces with the following property: for each i if all of the variables but v_i are held constant, then $f(v_1, \dots, v_n)$ is a linear function of v_i (Lang, 2002). It is easy to verify that Kronecker product, convolution, dot product are all special cases of multilinear map.

Figure 3 gives a schematic view of general structure of the MLM layer. The left factor and right factor are produced from the same input, which are later combined by the multilinear map to produce the output. Depending on the type of multilinear map used, the MLM layer will become HKD layer or KTP layer. We note that it is also possible to introduce more factors than two into an MLM layer.

4. Empirical Evaluation of Multilinear Map Layer

We next empirically study the properties and efficacy of the Multilinear Map layers and compare it with the case when no structural constraint is imposed on the output.

To make a fair comparison, we first train a convolutional autoencoder with the output layer being a fully-connected layer as a baseline. Then we replace the fully-connected layer with different kinds of MLM layers and train the new network until quality metrics stabilizes. For example, Figure 4 gives a subjective comparison of HKD layer with the original model on SVHN dataset. We then compare MLM layer method with the baseline model in terms of number of parameters and prediction quality. We do the experiments based on implementation of MLM layers in Theano (Bergstra et al., 2010, Bastien et al., 2012) framework.

Table 4 shows the performance of MLM layers on training an autoencoder for SVHN digit reconstruction. The network first transforms the 40×40 input image to a bottleneck feature vector through a traditional ConvNet consisting of 4 convolutional layers, 3 max pooling layers and 1 fully connected layer. Then, the feature is transformed again to reconstruct the image through 4 convolutional layers, 3 un-pooling layers and the last fully-connected layer or its alternatives as output layer. The un-pooling operation is implemented with the same approach used in (Dosovitskiy et al., 2014), by simply setting the pooled value at the top-left corner of the pooled region, and leaving other as zero. The fourth column of the table is the number of parameters in fully-connected layer or its alternative MLM layer. By varying the length of bottleneck feature and using different alternatives for FC layer, we can observe that both HKD and KTP layer are good alternatives for FC layer as output layer, and they also both significantly reduce the number of parameters. We also tested the case with convolutional layer as output layer, and the result still shows the efficacy of MLM layer.

Figure 3: Diagram of the structure of a MLM layer. the output of the preceding layer is fed into two nodes where left factor tensor and right factor tensor are computed. Then a multilinear map is applied on the left and right factors to construct the output.

(a) Original image patches selected from SVHN dataset

(b) Results of an Autoencoder A1

(c) Results of an Autoencoder A2 with less neurons in the bottleneck layer than A1

(d) Results of an Autoencoder with as many neurons in the bottleneck layer as A2 but uses HKD as output layer

Figure 4: This figures show the results of passing five cropped patched from SVHN dataset as input images through Autoencoders with different output layers. The first row contains the original images. The second row contains the output of an Autoencoder “A1”. The third row contains the output of an Autoencoder “A2”, which has smaller number of hidden units in the bottleneck layer. The fourth row contains the output of an Autoencoder “A3” constructed from “A2” by replacing the output FC layer with a HKD layer. It can be seen that “A3”, though with smaller number of hidden units in bottleneck layer, visually performs better than “A1” and “A2” in reconstruting the input images.

Table 1: Evaluation of MLM layers on SVHN digit reconstruction

model	bottleneck #hidden unit	total #params	layer #params	L2 error
conv + FC	512	13.33M	5764800	3.4e-2
conv + HKD	512	4.97M	46788	5.2e-4
conv + HKD multiple components	512	5.05M	118642	3.6e-4
conv + FC	64	13.40M	5764800	1.3e-1
conv+ HKD	64	5.04M	46788	1.8e-3
conv + KTP	64	5.04M	46618	3.2e-3
conv	16	5.09M	0	4.0e-2
conv + FC	16	13.36M	5764800	8.8e-2
conv + HKD	16	5.00M	46788	3.8e-3
conv + KTP	16	5.00M	46618	5.8e-3

As the running time may depend on particular implementation details of the KFC and the Theano framework, we do not report running time. However, the complexity analysis suggests that there should be significant reduction in amount of computation.

5. Related Work

In this section we discuss related work not covered in previous sections.

Low rank approximation has been a standard tool in restricting the space of the parameters. Its application in linear regression dates back to (Anderson, 1951). In (Sainath et al., 2013, Liao et al., 2013, Xue et al., 2013, Zhang et al., 2014b, Denton et al., 2014), low rank approximation of fully-connected layer is used; and (Jaderberg et al., 2014, Rigamonti et al., 2013, Lebedev et al., 2014b,a, Denil et al., 2013) also considered low rank approximation of convolution layer. (Zhang et al., 2014a) considered approximation of multiple layers with nonlinear activations. To our best knowledge, these methods only consider applying low-rank approximation to weights of the neural network, but not to the output of the neural network.

As structure is a general term, there are also other types of structure that exist in the desired prediction. Neural network with structured prediction also exist for tasks other than autoencoder, like edge detection(Dollár and Zitnick, 2013), image segmentation(Zheng et al., 2015, Farabet et al., 2013), super resolution(Dong et al., 2014a), image generation(Dosovitskiy et al., 2014). The structure in these problem may also exhibit low-rank structure exploitable by MLM layers.

6. Conclusion and Future Work

In this paper, we propose and study methods for incorporating the low-rank image prior to the predictions of the neural network. Instead of using regularization terms in the objective function of the neural network, we directly encode the low-rank constraints as structural constraints by requiring the output of the network to be the result of some kinds of multilinear map. We consider a few variants of multilinear map, including a hybrid-Kronecker-dot product and Kronecker tensor product. We have found that using the MLM layer can significantly reduce the number of parameters and amount of computation for autoencoders on SVHN.

As future work, we note that when using ℓ_1 norm as objective together with the structural constraint, we could effectively use the norm defined in Robust Principal Value Analysis as our objective, which would be able to handle the sparse noise that may otherwise degrade the low-

rankness property of the predictions. In addition, it would be interesting to investigate applying the structural constraints outlined in this paper to the output of intermediate layers of neural networks.
